

LC 73- set matrix zero

Approach:

- Find the length of row and column
- Create two flags firstrowzero and firstcolzero, initialize as false, they will be the base for next operations
- Find if first row and first column have 0 , if yes then change the flags to true
- If first row has a 0 then convert all row elements into 0
- If first column has 0 convert all elements into 0
- Using first row and column as mark points of 0 , convert all mark points $[i][0]$ and $[0][j]$ has 0

LC 73- set matrix zero

Approach:

- Initialize an array/list with [1] as first element
- For each new row:
 - start with 1
 - then for each j in the middle compute $prev[j-1]+prev[j]$
 - end with 1

LC 73- set matrix zero

Approach:

- Find the pivot, traverse the array from left to right, find first index such that $nums[i] < nums[i+1]$. if no index exists then array in descending order, reverse it.

- Find successor by traversing again, find j such that $\text{nums}[j] > \text{nums}[i]$
- Swap $\text{nums}[i]$ with $\text{nums}[j]$
- Reverse subarray from $i+1$ to get the smallest lexicographic order.
